# decrement vs decrement!

## decrement(attribute, by = 1)

Initializes `attribute` to zero if `all` and subtracts the value passed as `by` (default is 1). The decrement is performed directly on the underlying attribute, no setter is invoked. Only makes sense for number-based attributes. Returns `self`.

Source: [hide](#) | on GitHub

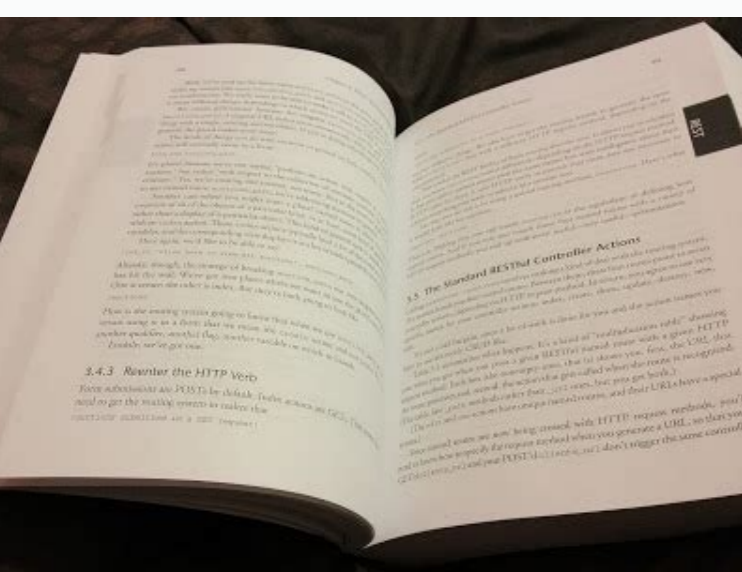

```
# File rails/activerecord/lib/active_record/connection_adapters/abstract_adapter.rb, line 232
def decrement(attribute, by = 1)
  self[attribute] ||= 0
  self[attribute] -= by
  self
end
```

## decrement!(attribute, by = 1)

Wrapper around `decrement` that saves the record. This method differs from its non-bang version in that it passes through the attribute setter. Saving is not subjected to validation checks. Returns `self` if the record could be saved.

Source: [hide](#) | on GitHub

```
# File rails/activerecord/lib/active_record/connection_adapters/abstract_adapter.rb, line 233
def decrement!(attribute, by = 1)
  decrement(attribute, by):update_column(attribute, self[attribute])
end
```

### Validation Helpers :

## presence (2/2)

- empty or whitespaces
- "can't be empty"

```
class Person < ActiveRecord::Base
  validates :is_admin, :presence => true
end
```

a boolean field → false blank? is true

```
class Person < ActiveRecord::Base
  validates :is_admin,
    :inclusion => { :in => [true, false] }
end
```

### Adding a Feature to enum

```
module StatefulEnum
  module ActiveRecordExtension
    def enum_definitions, &block
      enum = super.definitions

      if block
        enum.each_key do |column|
          states = enum_definitions[column]
          StatefulEnum::Machine.new(self, column, &block)
        end
      end
    end
  end
end
```

```

When we create a new Rails project, we can use ActiveRecord to validate our data. However, when it is called the saved method, validations will be made). ActiveRecord validation helpers ActiveModel::Validations provides us with a list of predefined validation helpers with easy-to-use simple error messages. For the attribute of: number, use the number validation helper to ensure that it was given a numerical value and that is as much greater than 0 and less than 100. Instead of relying implicitly on validation to execute automatically by the previous methods, you can execute validation yourself. These provide us common validations, we want to verify, as the presence of data, data duration and the uniqueness of data. Here are some of them: Acceptance: If we use the check boxes, we can use this method to see if a user checked the check box. Validates association: This validation can be used to validate associations. Confirmation: We can use this validation to make sure that two text fields have the same entry exactly (ex: creating a password or email). / Inclusion: This checks if certain values are not included or excluded from the values of an attribute. Format: Validate the format of an attribute value (ex: Date A e a E 'mm / dd / yy). â, ~ "This assistant validates the duration of a user's entry. Therefore, we must add these validations to our model file. Model file with validation, I used the validity method. As you can see, the class of the Player has four attributes: Name, age, number of player and his position. Here the validations we want to add: The age of a player must have more than 18. A player number must be between 1 and 99. The player's name must be present. Demo 1: Add similar validations that mentioned that we are using model level validations. returns false. Method to verify the validity of data. We need to implement it! For the next step we move to our controller. ApplicationController when a user tries to create a new player n'âcadilav al a ralmis arenam ed Y .otsecnolab ed serodaguj soveun raerc arap oiralumrof nu y etnemairotaela sodaercorp otsecnolab ed serodaguj ed atsil anu somenet AûqA.serodaguj soveun raerc arap oiralumrof y anigjâp ecidnI.otsecnolab ed serodaguj arap sollices selfrep raerc y rartson ne etsisnoc euq sliarR otceyorp oveuN .solradraug ed setna socinâA naes sotad sol euq arugesa otsE l l cA sseneuqinu.on o n'âicamrofni atse ecudortni oirausu le is aberupmoc etnaduya etsE "âAeA ecnesba /ecneserp.socr©Ammun serolav agnetnoc adartne al euq arugesa otsE "âAeA ytlaciremun jsiy ni;munixam;munimim:omoc selat senoicirtser sarto noc esranibmoc edeup otsE( .setneserp n'âtse is rartnoc somadrop euq serortse sol somerartson .rotcudorper oveun nu raerc arap oiralumrof ortseun rartson ed setna .rev edeup onoCanigjâp aveuN anigjâp aveuN artseun ne artneucne es euq oiralumrof ortseun a oloân@Aida:âa somecach oL .amargorp le noc n'ârautacretni soirausu solse on'âc ranimreted somedop on .ograbme niS d'ilav .odnauc sodadraug rotte ed sejasnem ed atsil anu yah .Jam 'âllas ©Aûq raugireva arap? d'ilav# le somas secnotE,â eman:no notaidiv drocER evitcA odnatuceje jâtse roiretna ogid!âc IE eslaf => # .eslaf evleuved .oirartnoc ol od .andec anu se adartne al is eurt evleuved .serodamarqorp sol .sorsotom onoc nesneip sorto euq rimusa somedop oN .ozalp ogral a serorre sohcum rasuc edeup otse .sotad ed esab artseun a sodi!âv on sotad nagerga es IS .siâmed sol ne odnasrep somiurtsoncol .sel venoicacila y samargorp somibircse odnauc .sotad ed esab al a n'ârida:âa es sotad sol ednoc otup le se etaec odot©Am IE .sodi!âv sotad noc odaneler oiralumrof:sodi!âv sotad somibircse is ograbme niSnaâvne es euq sodi!âvni sotadnaâvne es euq sodi!âvni sotad ed olpmeje nu yah AûqA.ednarg ogor otet nu ne serorre jârev .sodi!âvni sotad enoitnoc euq oiralumrof nu raivne odatmetni ah ay oirausu le is .ograbme niS .etaerc odot©Am la jâramall es .oiralumrof nu aâvne I use the same validation assistant to make sure the player has 19 years or more. 2: Implementation of the validation that we have defined ours We can display each error that is held with the flash hash. This is will refer back to validations we defined in the model file. If none are present, no error will pop up instead the form will display like normal. method. If it passes, the instance will be save, thus added to the database. You can also use .invalid?, which is the reverse of the .valid? This new players will be added to the list on the index page. This means that whenever a user tries to add or update data through Ruby on Rails, the program will run validations first to check whether or not the data should be persisted into the database.(Important to note: Validations will not occur if an ActiveRecord object calls the new method because this object is not interacting with the database. These validations would be triggered when database activity happens. This is why validations are super important!Model-level validations is the best way to prevent invalid data from being saved. We can expect that other users use our programs and applications. After adding that error or those errors, the user is redirected to the form so that they can try again.Step 3: Displaying ErrorsAfter implementing, we need to be able to display these errors to the user if any do occur. And updated index page.Our data passes all validations and we can see that our instance was successfully added to the database! If it is not valid, the .save method will not be called. Here are a few examples to get the hang of different validation methods used in Rails: class Person < ApplicationRecord validates :name, presence: true end => p = Person.new # => # => p.errors.messages # => {name:"can't be blank"} => p.save # => false => p.save! # ActiveRecord :: RecordInvalid: Failed Validation: Name cannot be blank => Person.create! # => ActiveRecord :: RecordInvalid: Failed Validation: Name cannot be blank For more information on validating active record on rails, see the official guide. It is at this point that we want to validate our data before it is in the database. In ActiveRecord, validations are special methods that prevent data from the "ADB data from becoming a database. Note the following code: Class Person true person.create (name: nil). Valid? First we create a new instance. These error messages can be accessed using the method.Mistake.Messages. This method takes two arguments: the attribute to the validation hash of options detailing how we should validate this attribute validate a player name. I validated the attribute: name and used the presence validation helper to make sure that a name is typed in the text field of the form. If it is not, an error(s) will be added to the object that we can temporarily contain in Flash Hash .
